Abstract

This report presents the Danish Design Reference Year based on observed data from 2001 – 2010. In various sectors - i.e. building and construction, energy, etc. - the climate and weather usually plays a part in a given project. The Danish Design Reference Year dataset is a collection of data series for eleven specific parameters, that each represents a *typical* year in Denmark. The uses of the dataset may vary from simulations to statistical analysis, graphical overviews etc.

The Danish land areas have been sectionalized into five to six climatological zones depending on the parameter, each characterized by distinct diurnal and yearly variations. The dataset consists of observed data from one station located within and representing each zone.

The parameters included in the dataset are temperature, relative humidity, wind speed and direction, atmospheric pressure, global radiation, cloud cover, soil temperature, sea temperature, diffuse irradiance and illuminance. The time resolution is hourly except for soil temperature where the resolution is daily values.

In addition to the complete Danish Design Reference Year dataset, a subset specifically selected to be used for energy performance calculations for obtaining a building permit is included.

Preface

This report presents the collective Danish Reference Year dataset, previously published in the two distinct reports in Danish language only:

[1] *DMI Technical Report 12-17: 2001-2010 Design Reference Year for Denmark*, by Peter Riddersholm Wang, Mikael Scharling and Kristian Pagh Nielsen, 2012

[2] *DMI Technical Report 13-18: 2001-2010 Dansk Design Reference Year – Supplerende datasæt*, by Peter Riddersholm Wang, Mikael Scharling Kim Bjarne Wittchen and Claus Kern-Hansen, 2013

Both projects were funded by the Danish Energy Agency, and the process involved the following collaborators:

- Danish Energy Agency
- Danish Meteorological Institute
- Danish Building Research Institute, Aalborg University
- Technical University of Denmark

1. Introduction

The Danish Design Reference Year (DRY) was last published in 1995 [3], presenting various climate data from the period 1975 – 1989. It is well known, that the climate of Denmark has since changed, hence the need for an updated reference dataset.

The purpose was – and still is – to produce a dataset from climate data, designed specifically to be used as input data for computer simulations of technical dimensioning i.e. in the energy and construction sector.

As part of this, a new dataset to be used for energy performance calculations for obtaining a building permit [4] is presented. Given the general rule that similar conditions apply for all locations in Denmark, it was decided that one dataset should represent the whole Denmark in this regard. This dataset should best represent most of the population in Denmark, and datasets from the three stations Holbæk Flyveplads, DMI and Sjælsmark were chosen.

In 2012 the project “Solar Resource Assessment in Denmark” [5] resulted in the above mentioned report [1], presenting an updated DRY dataset aimed at the solar energy sector in Denmark, including the parameters global radiation, relative humidity, temperature, wind speed, diffuse irradiance and illuminance. The project was funded by the Danish Energy Agency.

It was since expanded in 2013 with more parameters - still funded by the Danish Energy Agency – and published in a separate report [2], with a supplementary dataset consisting of the parameters wind direction, atmospheric pressure, cloud cover, sea temperature and soil temperature.

The present report presents the collective DRY dataset from the two reports. It is a collection of hourly (for ten parameters) and daily (for one parameter) climate data, spanning one calendar year for all eleven parameters and various locations across the country. It is constructed from monthly data from assorted years during the period 2001 – 2010, resulting in a complete calendar year of data.

Where the previously used DRY dataset consisted of data from two locations in Denmark, the updated dataset presented in this report has been expanded to cover five to six climatological zones in Denmark, each characterized by distinct diurnal and yearly variations. The zones each represent the climatological variations in a given area of Denmark for each of the eleven parameters, making it possible to tune the derived calculations depending on location.

The present report contains the following information on the DRY dataset:

- station metadata
- maps with zonal sections and station positions
- time series plots
- tables with simple statistical information
- attached .csv files with the hourly (daily) dataset

2. Data

The dataset consists of observations from the DMI station network, and has undergone a series of calculations and quality control procedures to meet specific requirements for the DRY dataset.

Parameters

The dataset include one year of hourly data for the following parameters:

- temperature (°C)
- relative humidity (%)
- wind speed (m/s)
- wind direction (°)¹
- atmospheric pressure (hPa)
- global radiation (W/m²)
- cloud cover (%)
- sea temperature (°C)
- diffuse irradiance (W/m²)
- illuminance (lux)

and one year of daily data for:

- soil temperature (°C)

Since diurnal variations in soil temperature in 1m depth are negligible, only daily mean values are included in the dataset for this parameter.

Interpolated values

Missing and/or erroneous values have been replaced with interpolated values from the nearest stations, which ensure complete time series. Interpolated values are clearly flagged, see section 18.

The reference year

As described above, the dataset contains one year of hourly or daily data. The dataset is not measured continuously throughout a specific year; rather it is constructed from monthly data from different years. Each month has been selected with the climatological premises in mind, that it should exhibit *typical* climatological variation. This means no extremes, yet some variation is indeed tolerated.

The reference year is constructed from twelve typical months during 2001 – 2010 and is shown below.

month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
year	2009	2009	2006	2010	2006	2005	2009	2009	2009	2008	2010	2009

Zones

In the same way that the reference year must represent a typical climatological year, each parameter must also exhibit typical climatological variations across the country. Consequently, Denmark has been sectionalized into five to six climatological zones depending on the parameter, each characterized by distinct diurnal and yearly variations, i.e. coastal areas might have very different diurnal variation than inland areas in spite of similar monthly averages.

The dataset consists of observed data from one station located within and representing each zone. When choosing a station to represent each zone, two main criteria needed to be fulfilled: firstly the location of the station should best represent the climatology in the zone and secondly the regularity of the observations should be as high as possible.

¹ 0° is quiet, 360° is wind from north, 90° is wind from east etc.

3. How to use the dataset

Using the dataset for a given location, one needs to determine – for each parameter – in which zone the location is situated. This can be done by inspecting the maps for each parameter in the following sections. When the zones are determined, the corresponding stations can be looked up in the station tables.

As an example, assume a building project in Hillerød needs to assess the corresponding datasets for temperature, wind speed, atmospheric pressure and global radiation for that specific location:

Looking through the maps and tables in the following sections, the zones and stations can be presented:

parameter	zone	station name	station no.
temperature	5	Holbæk Flyveplads	6156
wind speed	4	Holbæk Flyveplads	6156
atmospheric pressure	4	Holbæk Flyveplads	6156
global radiation	5	Sjælsmark	6188

After downloading the dataset, the data series can easily be assessed in the files:

DRY_temperature_hourly_6156.csv
DRY_wind_speed_hourly_6156.csv
DRY_pressure_hourly_6156.csv
DRY_global_radiation_hourly_6188.csv

4. Temperature

Data

The temperature dataset consists of hourly mean values from six stations.

12. Soil temperature

Data

The soil temperature dataset consists of modelled daily mean values from six stations.

Model

Since soil temperature in 1m depth changes slowly, the soil temperature is modelled as daily values. The temperature is modelled from measurements of soil temperature in 30 cm depth.

The climatological zones are identical to those of air temperature.

The model is chosen by the Danish Building Research Institute and is described in *Varmetab fra fjernvarmeledninger*, by B. Kvisgaard og S. Hadvig, 1980 [6] by the formulas:

$$T_D = T_{mean} + (T_{30f} - T_{mean}) \cdot e^{(-D\sqrt{\pi/(a\tau_0)})}$$

where

$$T_{30f} = T_{30cm} \text{ at time } \tau - D\sqrt{\tau_0/(4a\pi)}$$

and

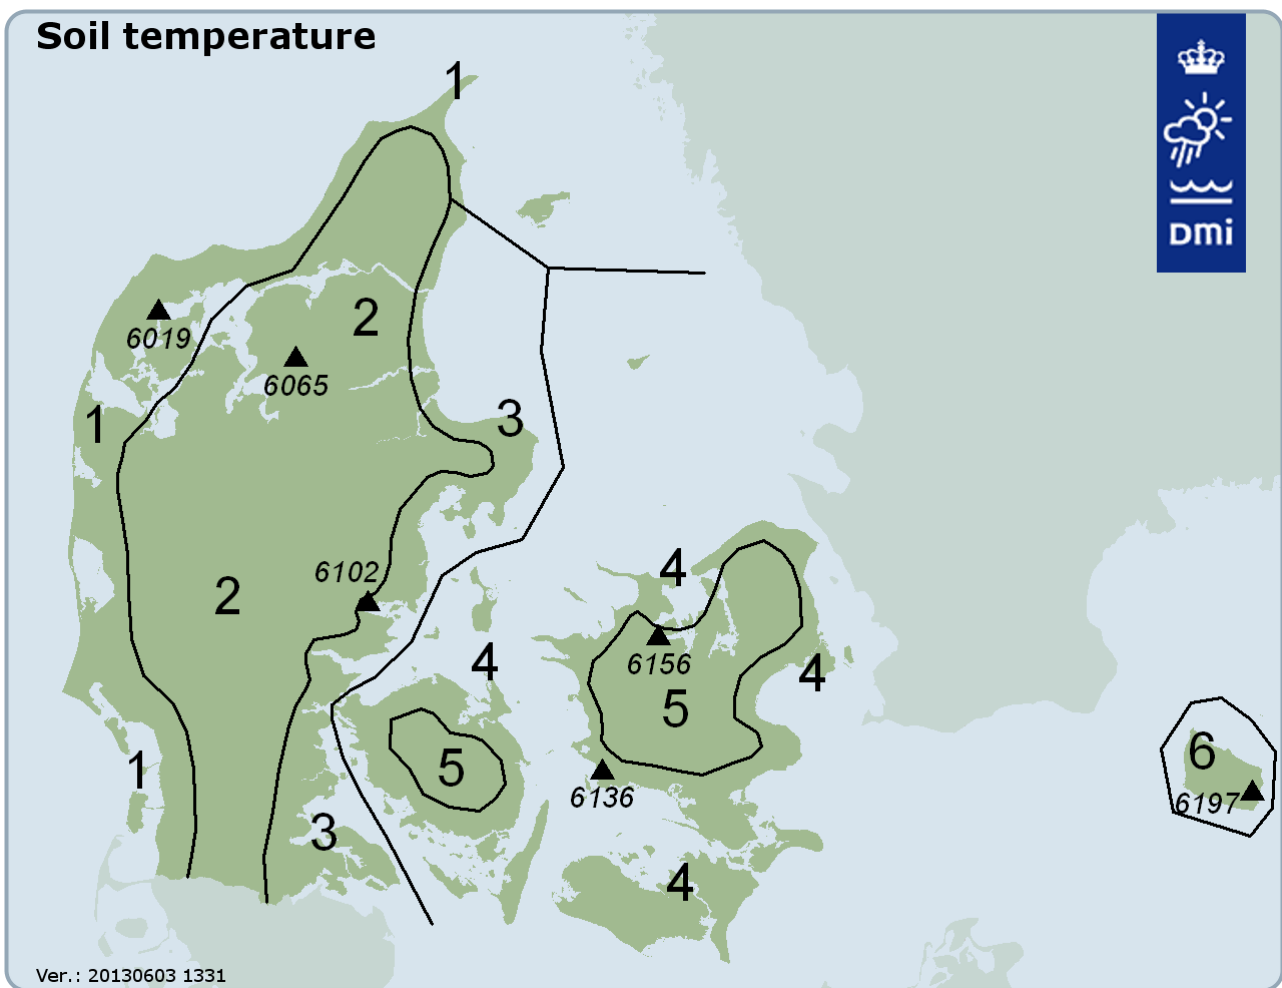

T_D	soil temperature in 1m depth ³
T_{mean}	yearly mean temperature in 30 cm depth
T_{30cm}	temperature in 30 cm depth
D	depth
τ	time in seconds after Jan. 1. 00:00
τ_0	period in seconds ($\sim 3,15 \cdot 10^7$ s)
a	soil temperature conductivity ($8,0 \cdot 10^{-7} \frac{m}{s}$)

³ Since the soil temperature in 30 cm depth is input to the model, a depth of 70 cm has been used.

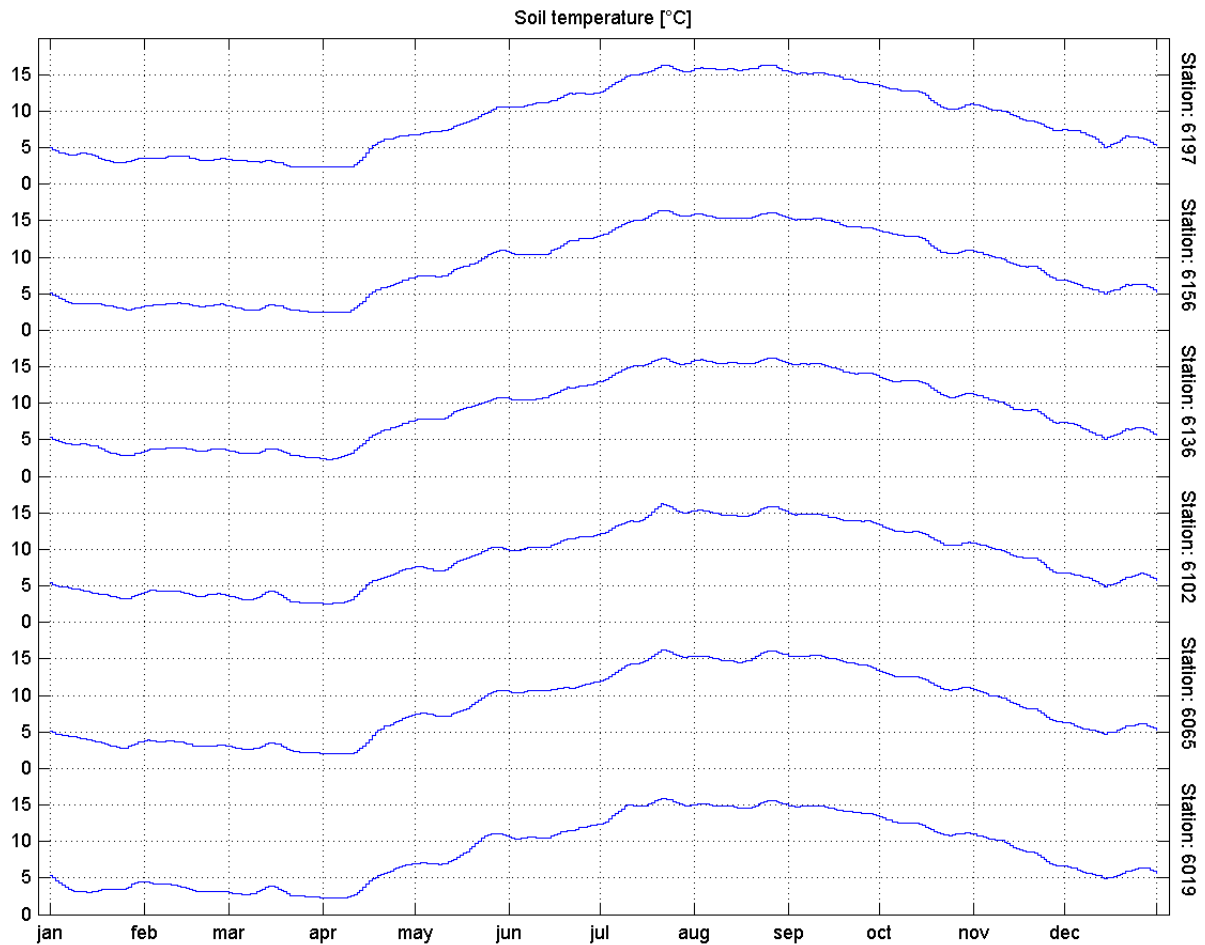

Stations and zones

13. Sea temperature

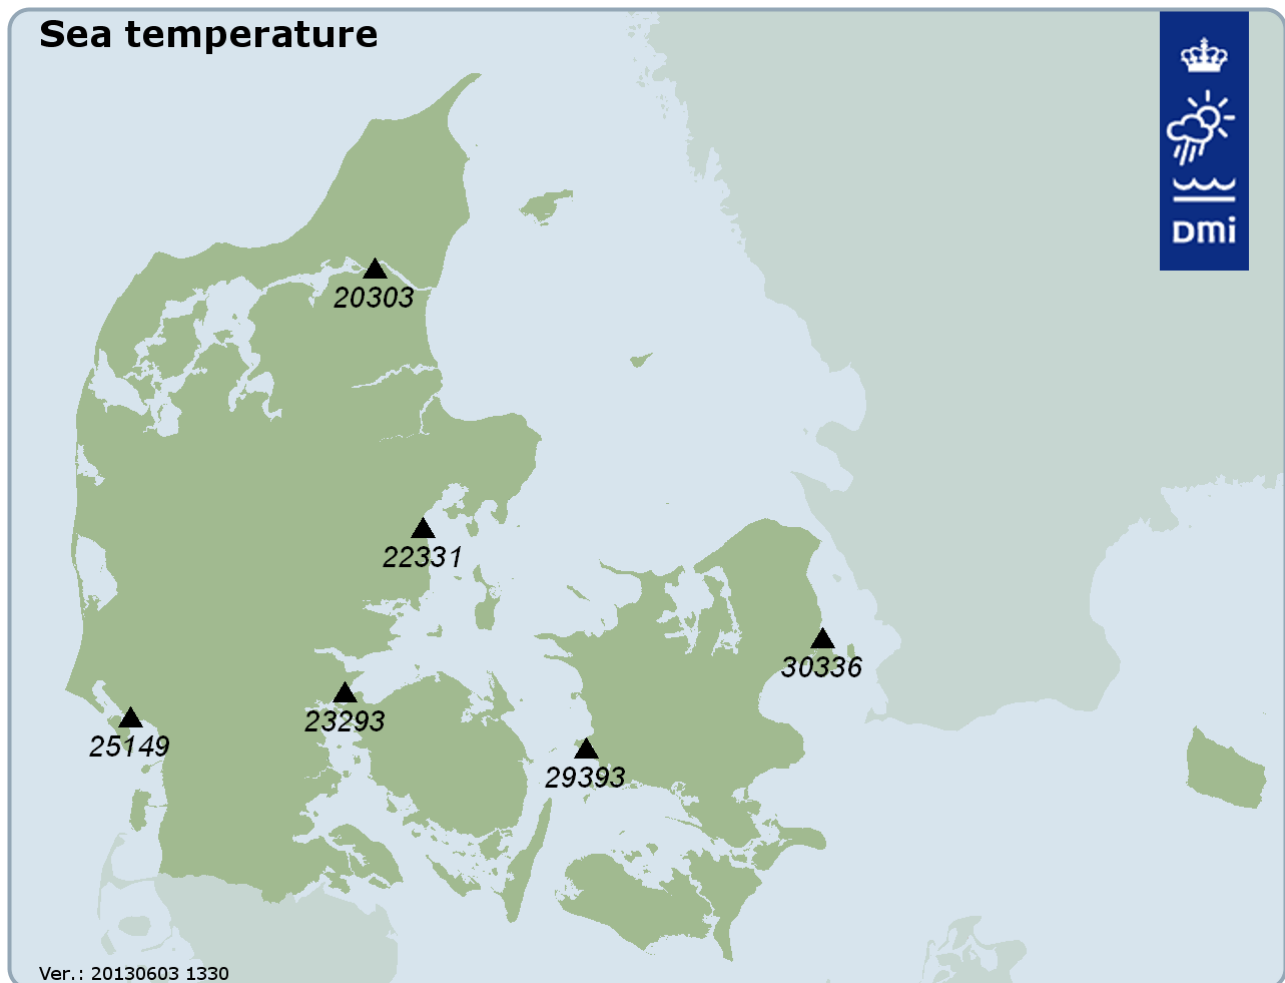

Since the dataset for sea temperature is measured in harbour basins, there are no zonal sections. The dataset from the harbour basins does not represent climatological variations in sea temperature, rather it describes the temperature variations within each basin.

Data

The sea temperature dataset consist of hourly mean values from six harbour basins.

Stations

Station name	Station no.	Latitude (°)	Longitude (°)

14. Diffuse irradiance

Diffuse horizontal irradiance is composed of the indirect radiation part of the global radiation, i.e. the radiation that is backscattered from the atmosphere, clouds etc.

The Technical University of Denmark has developed the method used to model the diffuse irradiance from the global radiation, see [7].

Data

The diffuse irradiance dataset consists of hourly mean values from six stations.

15. Illuminance

Modelled values of solar illuminance are presented below. The correlation between illuminance and global radiation is a function of the water content of clouds. The values have been calculated by The Danish Meteorological Institute [1, 8].

Data

The illuminance radiation dataset consists of hourly mean values from six stations.

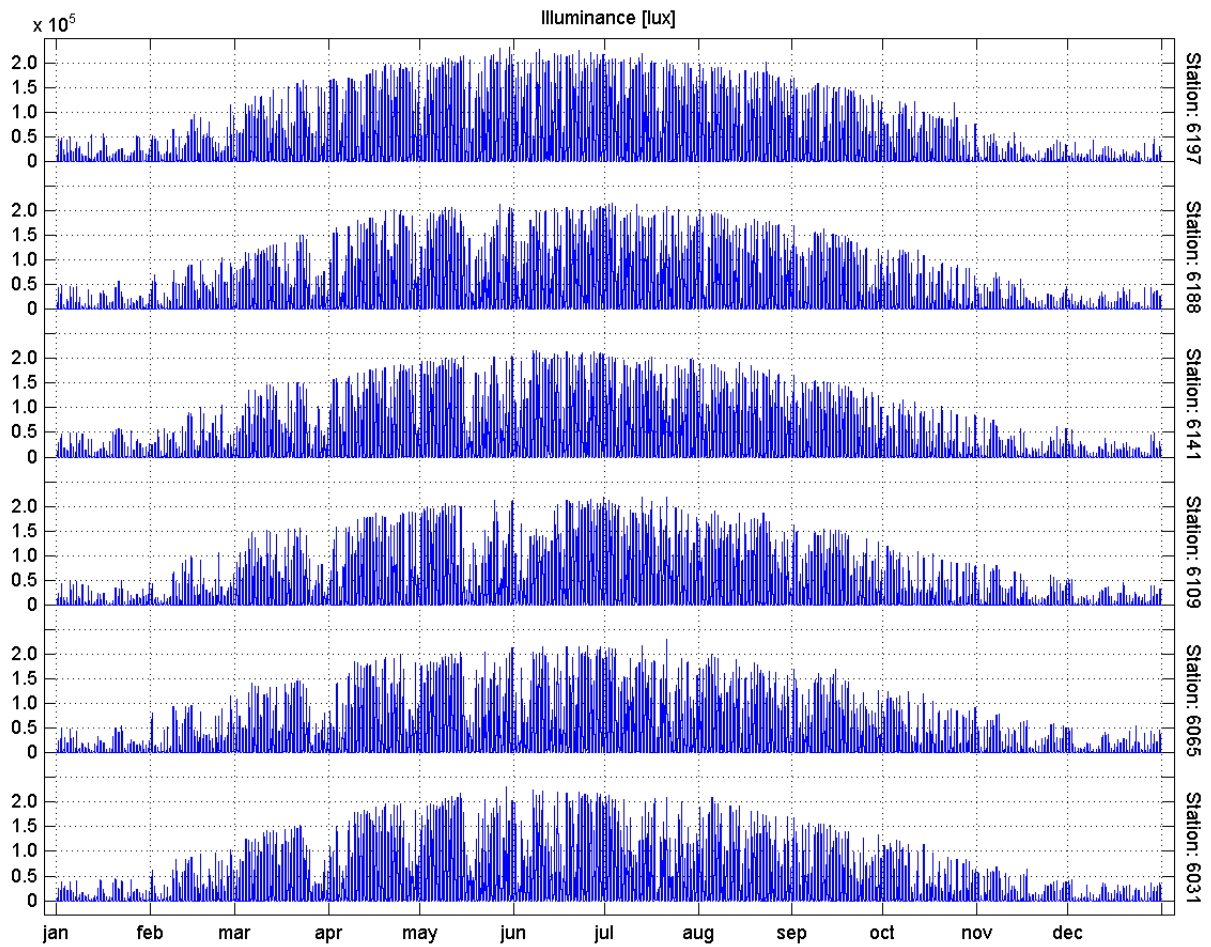

Stations and zones

16. Data for Building Permit Calculations

A dataset to be used for energy performance calculations for obtaining a building permit [4] is included.

Given the general rule that similar conditions apply for all locations in Denmark, it was decided that one dataset should represent the whole Denmark in this regard. This dataset should best represent most of the population in Denmark, and datasets from the three stations Holbæk Flyveplads, DMI and Sjælsmark were chosen.

This specific dataset is a subset of the DRY dataset, and thereby does not introduce any new data.

Data

The dataset consists of hourly mean values for the parameters temperature, relative humidity, wind speed and direction, atmospheric pressure, global radiation, cloud cover, diffuse irradiance and illuminance and daily values of soil temperature.

Stations

Station name	Station no.	Latitude (°)	Longitude (°)
Holbæk Flyveplads	6156	55,735783	11,603472
DMI	6184	55.716053	12.562150
Sjælsmark	6188	55,876457	12,412090

17. Quality Control

The quality control has been performed on all data in the dataset. The general method is described below, followed by a description of special cases of quality control for cloud cover and sea temperature.

General method

The dataset has been scrutinized on two levels:

1. A spatial control for daily, monthly and yearly data, performed by a contour mapping of Danish land area
2. A visual control of the time series from each station

Erroneous values have been replaced by interpolated values from nearby stations, to make sure the dataset is complete.

Special cases

In addition to the general quality control, some special cases of quality control had to be performed for cloud cover and sea temperature, as described below.

Cloud cover

In the cloud cover dataset, some values were missing, and the following values have been replaced:

station no.	station name	period	replaced with values from	
6060	Flyvestation Karup	12.11.2010 15:00 - 17.11.2010 07:00	6049	Hald vest
6141	Abed	20.11.2010 09:00 - 22.11.2010 09:00	6184	DMI
6184	DMI	15.01.2009 15:00 - 16.01.2009 17:00	6141	Abed
6184	DMI	03.06.2005 10:00 - 28.06.2005 06:00	6141	Abed

For station 6193 Hammer Odde Fyr all data in the months January 2009, February 2009 and November 2010 have been replaced with values from January 2008, February 2008 and November 2009 respectively.

Sea temperature

For station 30336 Københavns Havn all data in November 2010 have been replaced with values from November 2008.

18. Format

The collective dataset attached to this report consists of two zip-files.

- a. The DRY dataset (TR13-19_DRY.zip)
- b. The building permit dataset (TR13-19_building_permit.zip)

a. The DRY Dataset

The DRY dataset is attached as a zip-file containing a csv-file for each station and parameter in the format:

DRY_<parameter>_hourly_<statid>.csv

Hourly values for <parameter> and <station number>
format: Station number
Timestamp in UTC⁴ format *yyyymmddhh*
Value
Quality index (1100 indicates an observed value, 1000 indicates an interpolated value)

DRY_soil_temperature_daily_<statid>.csv

Daily values for soil temperature and <station number>
format: Station number
Timestamp in UTC² format *yyyymmdd*
Value
Quality index (1100 indicates an observed value, 1000 indicates an interpolated value)

b. The Building Permit Dataset

The dataset for obtaining a building permit contains a csv-file for each parameter in the same format as in "a. The DRY Dataset".

⁴ Universal Time, Coordinated: In Denmark, UTC+2 hours corresponds to summer time (daylight savings time) and UTC+1 hour otherwise.
